# NEW CYCLOPOID COPEPODS <br> ASSOCIATED WITH THE ALCYONARIAN CORAL TUBIPORA MUSICA (LINNAEUS) <br> IN MADAGASCAR 

By Arthur G. Humes and Ju-Shey Ho ${ }^{1}$

At Nosy Bé, in the northwestern part of Madagascar, several species of copepods (Humes and Frost, 1964) are known to be associated with members of the alcyonarian order Alcyonacea, but until now none have been reported living with members of the order Stolonifera.

While participating in the work of the U.S. Program in Biology of the International Indian Ocean Expedition at Nosy Bé in 1963-64, the first author collected 4 species of cyclopoid copepods from washings of Tubipora musica (Linnaeus), the common organ-pipe coral. These species are described below.

All figures have been drawn with the aid of a camera lucida.
The study of the material has been aided by a grant (GB-1809) from the National Science Foundation. We wish to thank Dr. Michel Pichon for verification of the identity of the coral and to acknowledge the many courtesies received from the staff of the Centre d'Océanographie et des Pêches at Nosy Bé.

[^0]
# Family Lichomolgidae Kossmann, 1877 

## Genus Lichomolgus Thorell, 1860

## Lichomolgus organicus, new species

Figures 1-30
Type material.-207 $\circ$ of, $98 \quad 0^{7} \sigma^{7}$, and 15 copepodids from a colony of Tubipora musica (Linnaeus), in 1 m , Pte. Ambarionaomby, Nosy Komba, near Nosy Bé, Madagascar, collected June 8, 1964: holotype ㅇ (USNM 113387), allotype (USNM 113388), and 144 paratypes (USNM 113389) ( 100 of and $44 \delta^{7} 0^{7}$ ) deposited in the United States National Museum, 80 paratypes ( 50 opo and $300^{7} 0^{7}$ ) in the Museum of Comparative Zoology, Harvard University, and the remaining paratypes in the collection of A. G. Humes.

Other specimens.-All from Tubipora musica collected in 1964: 8 ọ and $80^{7} \delta^{7}$, in 1 m , Pte. ì la Fièvre, Nosy Bé, Jan. $5 ; 1$ of, in 15 cm , Tany Kely, a small island south of Nosy Bé, Mar. 29; 4 우 and $80^{7} 0^{7}$, in 1 m , Pte. Ambarionaomby, Mar. $31 ; 15$ of and 1 $\mathrm{o}^{7}$, in 1 m , Pte. à la Fièvre, Apr. 15; and 14 of , in 2 m , Pte. Ambarionaomby, Sept. 27.
Female.-Body (fig. 1) with moderately broad prosome. Body length (not including setae on caudal rami) $0.99 \mathrm{~mm}(0.92-1.05 \mathrm{~mm}$ ) and greatest width (in middle of cephalosome) 0.49 mm ( $0.44-0.53$ mm ), based on 10 specimens. Ratio of length to width of prosome 1.5:1. Segment of first leg separated dorsally and laterally from head by a transverse furrow; lateral areas of this segment not expanded. Lateral areas of segments bearing legs 2 and 3 expanded and rounded posteriorly; those of segment of leg 4 smaller and somewhat truncated.

Segment of leg 5 (fig. 2) wider than long, $61 \mu \times 133 \mu$, with fifth legs borne laterally. Ventrally between this segment and the genital segment no apparent intersegmental sclerite. Genital segment (fig. 2) about as long as wide, $140 \mu \times 142 \mu$, in dorsal view expanded laterally in its midregion, posterior to which the segment is constricted so that its width at the posterior end is only $80 \mu$. Areas of attachment of egg sacs located dorsolaterally on posterior part of expansions. Each area (fig. 3) with 2 naked setae, 12 and $13 \mu$ in length; posterior to the setae a small rounded sclerotized protuberance. Three postgenital segments, each without ornamentation except for a few surficial hairs (sensilla), $37 \mu \times 67 \mu, 26 \mu \times 55 \mu$, and $28 \mu \times 51 \mu$, respectively, from anterior to posterior.
Caudal ramus (fig. 4) only a little elongated, $36 \mu \times 24 \mu$ in greatest dimensions, or 1.5 times longer than wide. Length along inner edge
to innermost distal seta $23 \mu$, along outer edge to base of lateral seta $23 \mu$, and to base of outermost distal seta $33 \mu$. Of the usual 6 setae, outer lateral seta naked and $66 \mu$ long; remaining 5 feathered: pedicellate dorsal seta $47 \mu$, innermost distal seta $115 \mu$, outermost distal seta $91 \mu$, and the 2 long median terminal setae, both "pegged," $169 \mu$ (outer) and $200 \mu$ (inner), and inserted between dorsal (unornamented) and ventral (with marginal row of spinules) flaps. In addition, a minute hyaline setule dorsally near insertion of outermost distal seta. Two hairs on dorsal surface of ramus.
Dorsal surface of prosome and dorsal and ventral surfaces of urosome with a few minute hairs. Ratio of length of prosome to that of urosome about 2.1:1.

All ovigerous females observed with broken egg sacs (one shown in fig. 5).

Rostral area (fig. 6) moderately well formed. At level of bases of second antennae a small longitudinal sclerotized ridge between rostrum and anterior part of labrum.

First antenna (fig. 7) 7 -segmented, with third segment showing ventrally a proximal sclerotized area suggesting an intercalary segment. Lengths of the segments, measured along their posterior nonsetiferous margins: $28 \mu$ ( $56 \mu$ along anterior margin), $95 \mu, 25 \mu, 50 \mu$, $50 \mu, 37 \mu$, and $22 \mu$, respectively. Formula for armature: $4,13,6,3$, $4+1$ aesthete, $2+1$ aesthete, and $7+1$ aesthete. All setae naked.

Second antenna (fig. 8) 4 -segmented, with last segment moderately elongated, $65 \mu$ along its outer edge, $39 \mu$ along its inner edge, and $27 \mu$ wide. Each of first 2 segments with a small inner seta, third segment with 3 setae ( 1 of them jointed), and last segment with 7 elements: 5 setae and 2 unequal recurved claws $45 \mu$ and $34 \mu$ long (measured along greatest axis). All setae naked.

Labrum (fig. 9) with 2 relatively short posteroventral lobes, free border of each lobe showing 2 small hyaline lamellae.

Mandible (fig. 10) with its basal region bearing on its posterior surface a small sclerotized area and separated by a constriction from its distal region, whose inner margin bears a prominent sclerotized pointed toothlike process followed by a striated fringe, whose outer margin has a row of slender spinules and which terminates in a long flagellum with lateral spinules. Paragnath (see fig. 9) a small lobe bearing inner hairs. First maxilla (fig. 11) a single segment bearing 2 terminal setae. Second maxilla (fig. 12) 2 -segmented, first segment unarmed, second segment produced distally and bearing row of 4-5 teeth (compare figs. 12 and 13) and slender naked terminal process. (If 4 such teeth, distalmost often slightly bifurcated; if 5, teeth all entire.) On postero-inner surface of second segment 2 setae, one finely pectinate along one margin, other bearing long bluntly tipped
setules along one side. A minute setule on proximal outer edge of this segment. Maxilliped (fig. 14) 3-segmented. Two naked setae on second segment. Third segment (fig. 15) bearing a naked seta, a setiform element with bifurcated tip, and a terminal process about $22 \mu$ long and clawlike, with a small hyaline lobe on each side of distal point.
Postoral area (fig. 16) only slightly produced ventrally; an incomplete line of sclerotization between bases of maxillipeds.

Legs 1-4 (figs. 17-20) with trimerous rami except for 2 -segmented endopod of leg 4. Armature of legs as follows (Roman numerals $=$ spines, Arabic numerals=setae):

| P 1 | protopod | $0: 1$ | $1: 0$ | exp | I:0 | I:1 | III,I, 4 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
|  |  |  |  | end | $0: 1$ | $0: 1$ | I,5 |
| P 2 | protopod | $0: 1$ | $1: 0$ | exp | I:0 | I:1 | III,I,5 |
|  |  |  |  | end | $0: 1$ | $0: 2$ | I,II,3 |
| P 3 | protopod | $0: 1$ | $1: 0$ | exp | I:0 | I:1 | III,I,5 |
|  |  |  |  | end | $0: 1$ | $0: 2$ | I,II, |
| P 4 | protopod | $0: 1$ | $1: 0$ | exp | I:0 | I:1 | II,I,5 |
|  |  |  |  | end | $0: 1$ | II |  |

Inner seta on coxa of legs 1-3 long and plumose, but in leg 4 short $(17 \mu)$ and naked. In first 3 pairs of legs inner margin of basis with short row of hairs, but such hairs absent in leg 4 . In all 4 legs setae on inner side of last segment of exopod with lateral hairs shorter proximally than distally. Spine on last segment of endopod of leg 1 $24 \mu$ in length. Endopod of leg 4 shorter than exopod. First segment $33 \mu \times 25 \mu$ with inner distal plumose seta $41 \mu$ long. Second segment $61 \mu$ long (including 2 terminal spinous processes) and $23 \mu$ wide in basal half and $19 \mu$ wide in distal half, the 2 halves demarcated by very slight indentation. Along outer margin of both segments rows of minute spinules. Terminally second segment with a row of minute spinules near insertion of 2 unequal spines, both with spinulose fringes, outer spine $21 \mu$, inner $39 \mu$ long, ratio about 1:1.86.
Leg 5 (fig. 21) with free segment elongated and slightly arcuate in outline, $66 \mu \times 23 \mu$, with short stout spines along outer edge and extending around to distal ventral surface; bearing terminally 2 naked setae $35 \mu$ and $37 \mu$ in length. Seta on body near free segment slightly feathered with group of spines near its insertion.

Leg 6 probably represented by 2 setae near areas of attachment of each egg sac (see fig. 3).

Color in life in transmitted light rather translucid, eye red.
Male.-Body (fig. 22) resembling in general form that of female. Length (cxcluding ramal setae) $0.59 \mathrm{~mm}(0.85-0.92 \mathrm{~mm}$ ) and greatest width $0.32 \mathrm{~mm}(0.30-0.34 \mathrm{~mm})$, based on 10 specimens. Ratio of length of prosome to that of urosome 1.6:1.

Segment of leg 5 (fig. 23) $29 \mu \times 67 \mu$. Genital segment longer than wide, $164 \mu \times 122 \mu$ in greatest dimensions, and in dorsal view rather bottle shaped, its lateral borders gently rounded. No intersegmental sclerite ventrally between these 2 segments. Four postgenital segments $18 \mu \times 45 \mu, 19 \mu \times 43 \mu, 15 \mu \times 40 \mu$, and $17 \mu \times 43 \mu$, respectively, from anterior to posterior.

Caudal ramus (fig. 24) resembling that of female, but slightly less elongated, its greatest dimensions $31 \mu \times 21 \mu$, or 1.48 times longer than wide.

Surfaces of prosome and urosome with minute hairs as in female. Ratio of length of prosome to that of urosome 1.56:1.

Rostral area like that in female.
First antenna resembling that of female, but an aesthete added on segments 2 and 4 (at exact points indicated by arrows in fig. 7), so that formula is $4,13+1$ aesthete, $6,3+1$ aesthete, $4+1$ aesthete, $2+1$ aesthete, and $7+1$ aesthete. Second antenna (fig. 25) more slender than in female, and last segment elongated, $68 \mu$ along outer edge, $52 \mu$ along inner edge, and $15 \mu$ wide. First segment with inner crescentic row of small spinules. Second segment with numerous small spinules along inner surface, arranged in 2 groups proximal and distal to seta. Last segment with row of very small spinules along inner surface. Armature like that of female, but 2 claws more nearly equal in length ( $34 \mu$ and $35 \mu$ ), though posterior claw more slender than other.
Labrum, mandible, paragnath, first maxilla, and second maxilla like those in female. Maxilliped (fig. 26) 4-segmented (assuming that proximal part of claw represents fourth segment). First segment unornamented. Second segment bearing on medial surface 2 setae and 2 rows of long spinules. Small third segment unarmed. Slender slightly recurved terminal claw $178 \mu$ in length (measured along axis), with narrow terminal lamella, smooth lamellar fringe along its concave surface, and 2 setae near its base, one on posterior surface $44 \mu$ long and finely barbed, other on anterior surface $17 \mu$ long, naked, and hyaline. Suggestion of division about midway along claw.

Postoral area resembling that of female.
Legs 1-4 resembling those in female and with same spine and setal formula, except for endopod of leg 1 (fig. 27), which has arrangement of $0: 1 ; 0: 1 ; I, I, 4$. On last segment of this endopod 2 spines, outermost of setae in female being here replaced by a spine; outer spine $29 \mu$ long, inner spine $43 \mu$ long and recurved distally, and both spines with strong lateral spinules. In alcoholized specimens last segment of endopod flexed outwardly. Terminal spines on endopod of leg 4 in one male $19 \mu$ (outer) and $51 \mu$ (inner), in another $16 \mu$ and $37 \mu$, with an average of $17.5 \mu$ and $44 \mu$, ratio of $1: 2.5$.

Leg 5 (fig. 28) with free segment elongated and slender, $36 \mu \times 9 \mu$, with nearly parallel sides in dorsal view, and with 2 terminal setae unequal, outer $31 \mu$ and inner $19 \mu$ long. Few minute spinules on outer distal surface of segment. No spinules near insertion of seta on body near free segment.
Leg 6 (fig. 29) a posterolateral flap on ventral surface of genital segment bearing 2 naked setae $23 \mu$ and $25 \mu$ long.

Spermatophore (fig. 30) inside body of male about $148 \mu \times 68 \mu$ plus neck of $14 \mu$.

Color in life resembling that of female.
Etymology.-The specific name organicus, from Latin, relating to musical instruments, refers to the association of this species with the organ-pipe coral Tubipora musica.

Comparison with related species.-Among those species in the large genus Lichomolgus, wherein the mandible has been described, there are 3 that, like L. organicus, show a prominent toothlike process on the proximal inner margin of this appendage. From these, L. organicus may be readily distinguished. In L. actinophorus Humes and Frost (1964) there is a single claw on the last segment of the second antenna, the free segment of leg 5 in the female is somewhat irregular and has a ratio of 2.1:1, the caudal ramus of the female has a ratio of $3.5: 1$, and there is a setiferous sphere on the second segment of the second maxilla. In L. decorus Humes and Frost (1964) there is one claw and one clawlike spine on the last segment of the second antenna, the last segment of the exopod of leg 4 has the formula III,I,5, and the free segment of leg 5 in the female is $2.2: 1$ with a basal expansion. In L. protulae Stock (1959) the shape of the body is transformed, there are 3 strong claws and 2 setiform claws on the last segment of the second antenna, the caudal ramus of the female has a ratio of about 8.3:1, the free segment of leg 5 in the female is about 2.1:1, and the toothlike process on the mandible is directed distally rather than proximally as in $L$. organicus. In addition, the females of L. actinophorus and L. protulae are distinctly larger.

There are 8 species of Lichomolgus in which the form of the mandible is unknown. These may be separated from L. organicus, however, on the basis of other characters (in each case using the female, except in the last mentioned species where the female is unknown). In $L$. dentipes Thompson and A. Scott (1903) the formula for the last segment of the exopod of leg 4 is III,I,5 and the free segment of leg 5 has a prominent toothlike inner process. In L. elegans Thompson and A. Scott (1903) there is 1 claw on the second antenna and the body is larger ( 1.5 mm ) and more slender. In L. gigas Thompson and A. Scott (1903) there is one claw on the second antenna and the body is larger ( 2 mm ). In $L$. longipes (Sewell, 1949) leg 5 is very long (about

8:1) and the body is larger ( 1.63 mm ) and more slender. In $L$. rigidus Ummerkutty (1962) the formula for the last segment of the exopod of leg 4 is III,I,5 and the body is larger ( 1.25 mm ). In $L$. rotundus Sewell (1949) the free segment of leg 5 is short, swollen, and somewhat produced on the outer margin, with a ratio of about 2:1. In L. tenuicornis Brady (1910) the caudal ramus is about 7:1, the free segment of leg 5 has a small basal expansion, and the body is larger $(1.7 \mathrm{~mm})$. In L. vagans Gurney (1927) (based on the male), the body is larger $(1.07 \mathrm{~mm})$ and the last segment of the second antenna (Gurney, 1927, p. 466, fig. C) has a ratio of length of the outer margin to width of about 5.6 :1, thus being slightly more slender than in $L$. organicus, where the ratio is about 4.5:1.

Since we still do not know the taxonomic importance of the variation in many characters observed in Lichomolgus (such as the terminal armature of the second antenna, the armature of the exopod of leg 4 , the exact form of the mandible and leg 5 , etc.), we find it impossible in Lichomolgus to say with which species $L$. organicus is most closely related. Such a conjecture would seem to be premature in view of the apparent very incomplete knowledge of the species in this genus.

## Lichomolgus conjunctus, new species

Figures 31-36
Type material.-163 of and $250^{7} 0^{7}$ from a colony of Tubipora musica (Linnaeus), in 1 m , Pte. Ambarionaomby, Nosy Komba, near Nosy Bé, Madagascar, collected đune 8,1964: holotype of (USNM 113391), allotype (USNM 113392), and 89 paratypes (USNM 113393) (79 우 and $10 \sigma^{7} \sigma^{7}$ ) deposited in the United States National Museum, 45 paratypes ( 40 of 9 and $50^{7} 0^{7}$ ) in the Museum of Comparative Zoology, Harvard University, and the remaining paratypes in the collection of A. G. Humes.
Other specimens.-All from Tubipora musica collected in 1964:
 15 cm , Tany Kely, a small island south of Nosy Bé, Mar. 29; 8 of, in 1 m , Pte. Ambarionaomby, Nosy Komba, Mar. $31 ; 14$ of and $30^{7} 0^{0^{7}}$, in 1 m, Pte. à la Fièvre, Apr. 15; and 43 of, in 2 m, Pte. Ambarionaomby, Sept. 27.

In the description that follows, morphological features not specifically mentioned may be assumed to be essentially like those in $L$. organicus.

Female.-Body (fig. 31) with prosome more pointed anteriorly than in L. organicus. Length of body (without ramal setae) 0.80 mm $(0.72-0.87 \mathrm{~mm})$ and greatest width $0.38 \mathrm{~mm}(0.34-0.40 \mathrm{~mm})$, based on 10 specimens. Ratio of length to width of prosome 1.53:1.

Segment of leg 5 (fig. 32) $46 \mu \times 107 \mu$. Genital segment slightly wider than long, $110 \mu \times 115 \mu$, in dorsal view expanded laterally just behind its midregion, posterior to which segment is constricted, with width at posterior end of segment $60 \mu$. Each area of attachment of egg sacs, located dorsolaterally on expanded part of segment, bearing 2 naked setae and rounded protuberance (more prominent than in previous species). Three postgenital segments $25 \mu \times 53 \mu, 21 \mu \times 48 \mu$, and $23 \mu \times 46 \mu$, respectively, from anterior to posterior.

Caudal ramus (fig. 33) only slightly longer than wide, $28 \times 23 \mu$ in greatest dimensions, ratio of length to width $1.22: 1$. Length along inner edge to innermost distal seta $19 \mu$, along outer edge to base of lateral seta $19 \mu$ and to base of outermost distal seta $25 \mu$. Pedicellate dorsal seta apparently naked. Relative lengths of 6 setae approximately those of $L$. organicus.

Ratio of length of prosome to that of urosome 2.6:1.
Egg sacs on all ovigerous females broken.
Rostral area (fig. 34) slightly more elongated posteriorly than in $L$. organicus. Segments of first antenna $23 \mu(44 \mu), 97 \mu, 21 \mu, 46 \mu, 45 \mu$, $31 \mu$, and $20 \mu$ in length (measured as before) and arrangement of naked setae and aesthetes as in previous species. Second antenna resembling that of $L$. organicus, but last segment slightly more slender ( $63 \mu$ along its outer edge, $39 \mu$ along its inner edge, and $21 \mu$ wide). Larger claw $37 \mu$ long, and more slender claw $32 \mu$ in length.

Labrum, mandible, paragnath, and"first maxilla like those in $L$. organicus. Second maxilla closely resembling that species also, but pectinate seta on second segment slightly longer, reaching nearly to end of first tooth; in females studied 4-5 entire teeth, or 4 teeth with distalmost slightly bifurcated. Maxilliped resembling that of L. organicus, but subterminal setiform element apparently not as distinctly bifurcated at its tip.

Postoral area similar to that in previous species.
Legs 1-4 with same segmentation and spine and setal formula as in $L$. organicus. Spine on last segment of endopod of leg $127 \mu$ long. Endopod of leg (fig. 35) with the following dimensions: first segment $33 \mu \times 25 \mu$ with inner seta $40 \mu$ long, second segment $60 \mu \times 21 \mu$ (greatest width) and $18 \mu$ (least width) with 2 terminal spines $25 \mu$ (outer) and $54 \mu$ (inner) in length, the ratio about 2.16:1.

Leg 5 similar to that of L. organicus, dimensions of free segment about $63 \mu \times 24 \mu$.

Leg 6 (represented by 2 setae near attachment of egg sacs) like that in previous species.

Color in life resembling that of $L$. organicus.

Male.-Body (fig. 36) with prosome more pointed than in previous species. Body length (excluding setae on caudal rami) 0.71 mm $(0.65-0.76 \mathrm{~mm})$ and greatest width $0.27 \mathrm{~mm}(0.23-0.30 \mathrm{~mm})$, based on 10 specimens. Ratio of length of prosome to its width 1.5:1.

Segment of leg $525 \mu \times 66 \mu$. Genital segment $151 \mu \times 117 \mu$. Four postgenital segments $14 \mu \times 45 \mu, 16 \mu \times 42 \mu, 13 \mu \times 40 \mu$, and $17 \mu \times 42 \mu$, respectively, from anterior to posterior. Caudal ramus $25 \mu \times 21 \mu$, or 1.19:1.

Ratio of length of prosome to that of urosome 1.57:1.
Table 1.-Comparison of certain features of Lichomolgus organicus and L. conjunctus

| Characters | L. organicus | L. conjunctus |
| :---: | :---: | :---: |
| Female |  |  |
| body size anterior border of prosome | $\begin{aligned} & 0.99 \times 0.49 \mathrm{~mm} \\ & \text { rounded } \end{aligned}$ | $0.80 \times 0.38 \mathrm{~mm}$ more pointed |
| ratio of prosome to urosome | 2.1:1 | 2.6:1 |
| caudal ramus | $36 \mu \times 24 \mu$ (1.5:1) | $28 \mu \times 23 \mu$ (1.22:1) |
| genital segment | lateral indentations near middle (fig. 2) | lateral indentations further back (fig. 32) |
| second antenna | last segment $27 \mu$ wide, claws $45 \mu$ and $34 \mu$ | last segment $21 \mu$ wide, claws $37 \mu$ and $32 \mu$ |
| spine on last segment of endopod of leg 1 | $24 \mu$ | $27 \mu$ |
| spines on last segment of endopod of leg 4 | $21 \mu$ and $39 \mu(1: 1.85)$ | $25 \mu$ and $54 \mu(1: 2.16)$ |
| Male |  |  |
| body size anterior border of prosome | $\begin{aligned} & 0.89 \times 0.32 \mathrm{~mm} \\ & \text { rounded } \end{aligned}$ | $0.71 \times 0.27 \mathrm{~mm}$ more pointed |
| caudal ramus | $31 \mu \times 21 \mu$ (1.48:1) | $25 \mu \times 21 \mu(1.19: 1)$ |
| spines on last segment of endopod of leg 4 | $17.5 \mu$ and $44 \mu$ (1:2.5) | $18 \mu$ and $50 \mu(1: 2.8)$ |
| free segment of leg 5 | $36 \mu \times 9 \mu(4: 1)$ | $28 \mu \times 8 \mu(3.5: 1)$ |

Rostral area like that of female. First antenna resembling that of $L$. organicus, with same formula for setae and aesthetes. Second antenna also resembling that species; last segment $73 \mu$ along outer edge, $54 \mu$ along inner edge, and $14 \mu$ wide. Two claws ( $34 \mu$ and $35 \mu$ ) similar to those in L. organicus.
Labrum, mandible, paragnath, first maxilla, and second maxilla like those in female; in males observed 4 teeth on distal end of second
maxilla, last tooth slightly bifurcated or entire. Maxilliped and postoral area much like those in L. organicus.

Legs 1-4 resembling those of female with same spine and setal formula, except for sexual dimorphism in leg 1 (as in L. organicus). Two spines on last segment of endopod of leg 1 like those in previous species, outer $27 \mu$ and inner $40 \mu$ long. Two terminal spines on endopod of $\operatorname{leg} 418 \mu$ (outer) and $50 \mu$ (inner), ratio of 1:2.8.

Leg 5 resembling that of $L$. organicus, but free segment relatively slightly shorter, $28 \mu \times 8 \mu$.

Leg 6 similar to that in previous species, but 2 naked setae slightly longer ( $28 \mu$ ).

Spermatophores, seen only inside body of male, resembling those of L. organicus.

Color in life like that of female.
Etymology.-The specific name conjunctus, from Latin, meaning "closely related or bordering on," refers to the close similarity between this and the preceding species.

Comparison with related species.-L. conjunctus closely resembles L. organicus in general appearance, but a careful study shows certain constant and characteristic differences. These are summarized in table 1.

Association of the two lichomolgids with the alcyonarian.Both L. organicus and L. conjunctus were recovered after washing unbroken colonies of Tubipora musica in sea water to which about 5 per cent ethyl alcohol had been added. The exact habitat of the copepods is unknown, but there seems to be little doubt of their association with the alcyonarian in view of the large numbers of individuals recovered.

## Family Clausidiidae Embleton, 1901

## Genus Hippomolgus Sars, 1917

## Hippomolgus latipes, new species

## Figures 37-58

Typematerial.- 8 of from a colony of Tubipora musica (Linnaeus), in 1 m, Pte. Ambarionaomby, Nosy Komba, near Nosy Bé, Madagascar, collected Mar. 31, 1964: holotypic of (USNM 113395) and 4 paratypic $\circ$ 우, (USNM 113396) deposited in the United States National Museum; remaining 3 ơ (dissected) in the collection of A. G. Humes.

Other material.-Also from Tubipora musica: $1 \circ$, in 1 m , Pte. Ambarionaomby, Nosy Komba, June 8, 1964.

Female.-Body (fig. 37) with a rather harpacticoid appearance. Length (excluding setae on caudal rami) $1.13 \mathrm{~mm}(0.97-1.19 \mathrm{~mm})$
and greatest width $0.32 \mathrm{~mm}(0.27-0.37 \mathrm{~mm})$, based on 8 specimens. Ratio of length to width of prosome 1.65:1. Segment bearing leg 1 completely fused with head. Lateral areas of segments of legs 1-3 not produced; those of segment of leg 4 slightly angular posteriorly.

Segment of leg 5 (fig. 38) broad, $94 \mu \times 242 \mu$, with fifth legs borne posterolaterally. Between this segment and genital segment on ventral side a weak intersegmental sclerite. Genital segment (fig. 38) wider than long, $130 \mu \times 198 \mu$. In ventral view its lateral border (fig. 39) with a small notch near middle of segment and a more pronounced indentation posteriorly. Areas of attachment of egg sacs situated dorsolaterally in midregion of segment. Each area (fig. 40) bearing outwardly a rather hyaline flange and inwardly a slender seta $11 \mu$ long, a spiniform seta $8 \mu$ long, and 2 small spinous processes. On ventral surface of posterior half of genital segment a transverse row of prominent spinules. Three postgenital segments $78 \mu \times 135 \mu, 60 \mu \times 118 \mu$, and $91 \mu \times 91 \mu$, respectively, from anterior to posterior. Anal segment (fig. 41) bearing anteriorly 4 transverse rows of spinules, 2 rows ventrolateral and 2 ventral; along its posterior border near insertion of each caudal ramus a row of small spinules, this row continued on dorsal side.
Caudal ramus (fig. 42) $104 \mu \times 34 \mu$, or 3 times longer than wide. Minute basal outer spinule $3 \mu$ long. Outer lateral seta $22 \mu$ long and naked. Outermost terminal seta $41 \mu$ long, naked, and composed of 2 parts: a sclerotized proximal half and a more slender distal portion. Innermost terminal seta $57 \mu$ long and haired along inner side. Two long terminal setae $209 \mu$ (outer) and $462 \mu$ (inner), both basally "pegged" and bearing lateral spinules. Pedicellate dorsal seta $39 \mu$ long and naked. Dorsal surface of ramus with small hairs and refractile points as indicated in figure.

Dorsal surface of prosome and dorsal and ventral surfaces of urosome with scattered refractile points and hairs. Prosome slightly longer than urosome, ratio 1.1:1.

In single ovigerous female collected egg sac (fig. 43) $319 \mu \times 107 \mu$, extending a little beyond ends of caudal rami, with each egg about $40 \mu$ in diameter.

Rostral area (fig. 44) small and well sclerotized. Posterior to it, between bases of second antennae, a small circular sclerotization.

First antenna (fig. 45) 6 -segmented and relatively short and robust, its length about $143 \mu$. Lengths of segments measured along their posterior nonsetiferous margins: $15 \mu$ ( $39 \mu$ along anterior margin), $19 \mu, 28 \mu, 18 \mu, 13 \mu$, and $24 \mu$, respectively. First segment with 5 setae, proximal one lightly haired, distal one spiniform, with a row of scalelike spinules along one edge. On second segment 2 similar spiniform setae. All remaining setae naked. Each of last 3 seg-
ments with long prominent aesthete. Formula for armature: 5, 14, $9,4+1$ aesthete, $2+1$ aesthete, and $7+1$ aesthete. Only ornamentation on first antenna consisting of crescentic row of spinules on first segment.

Second antenna (fig. 46) 4 -segmented, last segment $32 \mu \times 19 \mu$ in greatest dimensions. Each of first 2 segments with a seta, third segment with a spine and 2 slender setae on its inner distal expansion, and last segment bearing 7 elements (a spine and 6 setae). Ornamentation indicated in figure, inner margins of third and fourth segments having rows of scalelike spinules.

Labrum (figs. 47, 48) ornamented with spinules as indicated in figures.

Mandible (fig. 49) bearing 3 terminal elements: a clawlike ventral (outer) spine with 1-2 spinous processes on its concave edge, a spine with lateral spinous projections on its basal half, and a slender barbed seta. No paragnath. First maxilla (fig. 50) bilobed, with 8 setae disposed in groups of 3,4 , and 1 . Second maxilla (fig. 51) 2 -segmented; first segment unarmed, second with outer haired seta and 2 inner barbed spinulose setae and terminating in a short clawlike process with at either side a setiform barbed process (these 2 processes perhaps setae but their articulation not evident). Maxilliped (fig. 52) 4 -segmented, first segment with inner barbed seta, second with 2 naked setae, third unarmed, and fourth (fig. 53) subterminally with small naked seta and terminally with minute spiniform process and fringe of spiniform ornamentations resembling a small fan.

Area behind mouth and between mouthparts (fig. 47) showing anteriorly a transversely elongated median lobe (lingua) with a few very minute lateral spinules, followed immediately by a transverse row of hairs in 2 groups. Posterior to this a row of prominent spinules, with at either end a cluster of hairs. Bases of maxillipeds joined by sclerotized lines. Postoral area between maxillipeds and leg 1 broadly protuberant, especially noticeable in lateral view.

Legs 1-4 (figs. 54-57) with 3 -segmented rami. Armature of legs as follows (Roman numerals=spines, Arabic numerals=setae):

| P 1 | protopod | $0: 1$ | $1: \mathrm{I}$ | exp | I:0 | I:1 | III,I,4 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
|  |  |  |  | end | $0: 1$ | $0: 1$ | I,3 |
| P 2 | protopod | $0: 1$ | $1: 0$ | exp | I:0 | I:1 | III,I,5 |
|  |  |  |  | end | $0: 1$ | $0: 2$ | II,I,3 |
| P 3 | protopod | $0: 1$ | $1: 0$ | exp | I:0 | I:1 | III,I,5 |
|  |  |  |  | end | $0: 1$ | $0: 2$ | II,II,2 |
| P 4 | protopod | $0: 1$ | $1: 0$ | exp | I:0 | I:1 | II,I,5 |
|  |  |  |  | end | $0: 1$ | $0: 2$ | II,II,1 |

Free edges of all 4 intercoxal plates with rows of long slender setules. Inner margin of basis of leg 1 (fig. 54) bearing spinulose
spine $25 \mu$ long, with near its insertion an outer row of spinules and an inner spiniform process with slightly bifurcated tip. In legs $2-4$ this margin more or less rounded and carrying only a row of hairlike setules. Terminal segment of endopod of leg 1 with 1 spine and 3 setae. Spinous processes at each side of insertion of spine either entire or bifurcated at tip. Ornamentation of legs indicated in figures.

Leg 5 (fig. 58) having an expanded free segment $83 \mu \times 53 \mu$ in greatest dimensions. Four elements borne on this segment consisting (from dorsal to ventral) of a finely barbed spine $39 \mu$ long, a naked seta $66 \mu$ long, a strong spinulose spine $44 \mu$ long, and a short weakly barbed spine $23 \mu$ in length. Along dorsal edge of segment a row of spinules. Seta borne on body dorsal to insertion of segment $40 \mu$ long and naked. (In dorsal or ventral view of undissected animal, segment of leg 5 appearing much less expanded than actually.)

Leg 6 probably represented by seta and spine near attachment of each egg sac (see fig. 40).

Color in life unknown.
Male..-Unknown.
Etymology.-The specific name latipes, from Latin, meaning "having broad feet," refers to the wide free segment of leg 5 in this species.

Comparison with related species.-Only a single species of the genus Hippomolgus, H. furcifer Sars (1917), has been known until now. This species was described on the basis of 3 females found free in 60 fathoms, muddy bottom, on the coast of Norway. Males of Hippomolgus are unknown, although Nicholls (1944, p. 46) has expressed the view that the male of Hersiliodes dubia Thompson and A. Scott (1903) is in reality a Hippomolgus. This opinion was followed by Krishnaswamy (1953), who reported males of Hippomolgus dubia from the plankton of Madras. It seems improbable to us, however, that Hersiliodes dubia is a Hippomolgus. The mandible, described by Thompson and Scott as having " 2 horizontal plumose projections and 2 plumose setae," is very different. Bocquet and Stock (1957) think it probable that a new genus should be created for Hersiliodes dubia.

Like Hippomolgus furcifer, H. latipes has a body form that is less cyclopoid and more harpacticoid, has a relatively short 6 -segmented first antenna with a prominent aesthete on each of the last 3 segments, lacks paragnaths, and has a generally similar structure of the second antennae, mouthparts, and legs 1-5.

There are, however, important differences between these 2 species (based of necessity on the female only). In H. latipes the first segment of the first antenna does not bear a spine such as described in $H$. furcifer. The mandible bears 3 terminal elements ( 2 spines and

1 seta) instead of 4, as in Sars' figure (pl. 82, m). The maxilliped is 4 -segmented, the last segment ornamented with a small fanlike fringe, instead of being 3 -segmented as in Sars' figure (pl. $82, \mathrm{mp}^{2}$ ). The armature of the last segment of the endopod of leg 1 is I, 3 instead of $I, I I, 3$ as in Sars' species. The free segment of leg 5 is expanded instead of being narrow as in $H$. furcifer. The caudal ramus is only 3 times longer than wide instead of about $13: 1$ as in the Norwegian species. The length of the female is 1.13 mm , instead of 1.40 mm as in H. furcifer.

## Hippomolgus cognatus, new species

Figures 59-69
Type material.-Holotype of (USNM 113397) from a colony of Tubipora musica (Linnaeus), in 1 m , Pte. Ambarionaomby, Nosy Komba, near Nosy Bé, Madagascar, collected Mar. 31, 1964, deposited in the United States National Museum.

Other material.- 2 of from Tubipora musica, in 1 m , Pte. à la Fièvre, Nosy Bé, Jan. 5, 1964, 1 of (USNM 113398) in the United States National Museum, the other (dissected) in the private collection of A. G. Humes.

Female.-Body (fig. 59) resembling that of $H$. latipes. Length (not including setae on caudal rami) 0.90 mm ( $0.82-0.95 \mathrm{~mm}$ ) and greatest width $0.29 \mathrm{~mm}(0.28-0.31 \mathrm{~mm})$, based on 3 specimens. Ratio of length to width of prosome 1.56:1.

Segment of leg 5 broad, $78 \mu \times 188 \mu$. Genital segment (fig. 60) only slightly wider than long, $120 \mu$ in length, $132 \mu$ wide in its anterior half, and $110 \mu$ wide in its posterior half, where sides in dorsal view are nearly parallel. Areas of attachment of egg sacs located dorsolaterally on midregion of segment. Each area (fig. 61) with a slender naked seta $22 \mu$ long, a spine $8 \mu$ long, and 2 spinous processes. Three postgenital segments $66 \mu \times 101 \mu, 60 \mu \times 91 \mu$, and $80 \mu \times 82 \mu$, respectively, from anterior to posterior.

Caudal ramus (fig. 62) $64 \mu \times 31 \mu$ in greatest dimensions, or 3 times longer than wide. Outer lateral seta $25 \mu$, outermost terminal seta $39 \mu$, innermost terminal seta $88 \mu, 2$ long terminal setae $220 \mu$ (outer) and $450 \mu$ (inner), dorsal seta $33 \mu$ long.

Ratio of prosome to urosome 1.17:1.
In single ovigerous female collected egg sac (fig. 63) $352 \mu \times 138 \mu$, reaching nearly to ends of caudal rami, with each egg about $47 \mu$ in diameter.

Rostral area (fig. 64) bearing 2 rows of minute denticles.
First and second antennae like those in $H$. latipes. Labrum (figs. 65,66 ) ornamented as indicated in figures. Mandible (fig. 67) bearing 3 terminal elements as in $H$. latipes, but these with different orna-
mentation, i.e., with spinous processes on both sides of 2 spines and with seta naked. Paragnath absent. First and second maxillae and maxilliped like those in $H$. latipes.

Area behind mouth and between mouthparts with median lobe (lingua) weakly developed. Postoral area between maxillipeds and leg 1 (fig. 65) less protuberant than in $H$. latipes.

Legs 1-4 with same spine and setal formula as in $H$. latipes, except for endopod of leg 1 being $0: 1 ; 0: 1 ; 1,4$. Leg 1 (fig. 68) with inner spine on basis $22 \mu$ long and adjacent spiniform process asymmetrically bifurcated; terminal segment of endopod with 4 setae and with 3 small and rather obtuse processes between spine and first seta. Legs 2-4 resembling those of $H$. latipes.

Leg 5 (fig. 69) with relatively slender free segment, $61 \mu$ along inner and ventral margin, $51 \mu$ along outer and dorsal margin, and $22 \mu$ wide. Armature from dorsal to ventral consisting of spine $21 \mu$, seta $50 \mu$, spine $25 \mu$, and spine $40 \mu$ in length, all ornamented as in figure.

Leg 6 probably represented by spine and seta near attachment of each egg sac (see fig. 61).

In other respects similar to $H$. latipes.
Color in life unknown.
Male.-Unknown.
Etymology.-The specific name cognatus, from Latin, meaning "related or closely allied," refers to apparent close relationship between this species and $H$. latipes.

Comparison with related species.- $H$. cognatus differs from H. furcifer Sars (1917) in lacking a spine such as described on the first segment of the first antenna in the Norwegian species, in having 3 terminal elements instead of 4 on the mandible, in having a 4 -segmented maxilliped with a terminal fanlike fringe, in having the last segment of the endopod of leg 1 armed as I,4 instead of I,II, 3 as in Sars' species, and in having a relatively much shorter caudal ramus, 3:1 instead of $13: 1$ as in $H$. furcifer. The length of the female is 0.90 mm instead of 1.40 mm as in the species described by Sars.
H. cognatus apparently is closely related to $H$. latipes but differs from it chiefly in the form of the genital segment, the presence of denticles on the rostral area, the form and ornamentation of the labrum, the ornamentation of the 3 elements on the mandible, the armature of the last segment of the endopod of $\operatorname{leg} 1$, and the form of the free segment of leg 5 .

Association of the two clausidids with the alcyonarian.Whether Hippomolgus latipes and $H$. cognatus live in a close association with Tubipora musica or occur only sporadically in the coral colony
is difficult to determine on the basis of the relatively few specimens collected. (No Hippomolgus were found in 4 other colonies of Tubipora musica.)
